

Nancy & Laura, here is the water result discussion for the (b) (6) results. Note that one sample was collected before treatment and exceeded secondary MCLS for iron and manganese. However the sample collected after treatment did not exceed anything.

-Ed.

The test results for your well water were compared to the National Drinking Water Standards, otherwise known as the Maximum Contaminant Levels (MCLs). The results of the analysis are provided in the enclosed table. Though these standards do not apply to private domestic water wells such as yours, we have included the enclosed table so that you may compare the results with the Drinking Water Standards. **None of these metals were present in the water sample(s) collected from your property above a level of concern for human health exposure.**

EPA has also established National Secondary Drinking Water Regulations that set non-mandatory water quality standards for 15 contaminants. EPA does not enforce these "secondary maximum contaminant levels". They are established only as guidelines to assist public water systems in managing their drinking water for aesthetic considerations, such as taste, color and odor. These contaminants are not considered to present a risk to human health at the secondary maximum contaminant level.

The concentration of iron in your well water collected before treatment (GKMTW12_080915) was above the secondary maximum contaminant level for iron which is 300 µg/L. Iron is an essential element for human nutrition; however, high iron can cause constipation and other gastrointestinal effects. In addition, high iron may stain household fixtures and impart a metallic taste and red color to the water.

The concentration of manganese in in your well water before treatment (GKMTW12_080915) was above the secondary maximum contaminant level of 50 µg/L. High manganese can impart an unpleasant taste and odor to drinking water and can cause mineral deposits on plumbing features. The EPA Health Advisory for manganese is available at this location:
